The so-called *C*/*k* value is calculated by the step size *C* divided by the ratio *k* of the current transformer. It is clear that a capacitor with, for instance, 50 kvar may not be switched in if the power factor relay measures a deviation of just 10 kvar reactive power with regard to the preadjusted power factor target.

the capacitor is charged with electrons. These electrons in the charged capacitor will gradually leak through the dielectric until both conductor plates have an equal charge. The capacitor is then discharged. The ability to store electrons is called capacitance. Capacitance is specified in Farads. A 1-Farad capacitor connected to a 1

Motor Start Capacitors The primary purpose of a motor start capacitor is to briefly increase the motor starting torque as well as to allow a motor to be cycled on and off very quickly.. Motor Run Capacitors Motor run capacitors will then operate after the circuit is started. Using a motor run capacitor will run the motor with greater efficiency.

Time Constant of a Capacitor is the time taken by a Capacitor to charge to 63.2% of the applied voltage when charged through a known resistor. If *C* is Capacitance, *R* is a known Resistor, then Time Constant *TC* (or Greek Alphabet Tau - τ) is given by τ = *R*×*C*.
